Seismic illustrations of the basin-scale structure and stratigraphy of the southwestern Black Sea margin. (a) Karadeniz-Limankuy line and (b) Akzakoca line. (Location on Figure 1b).

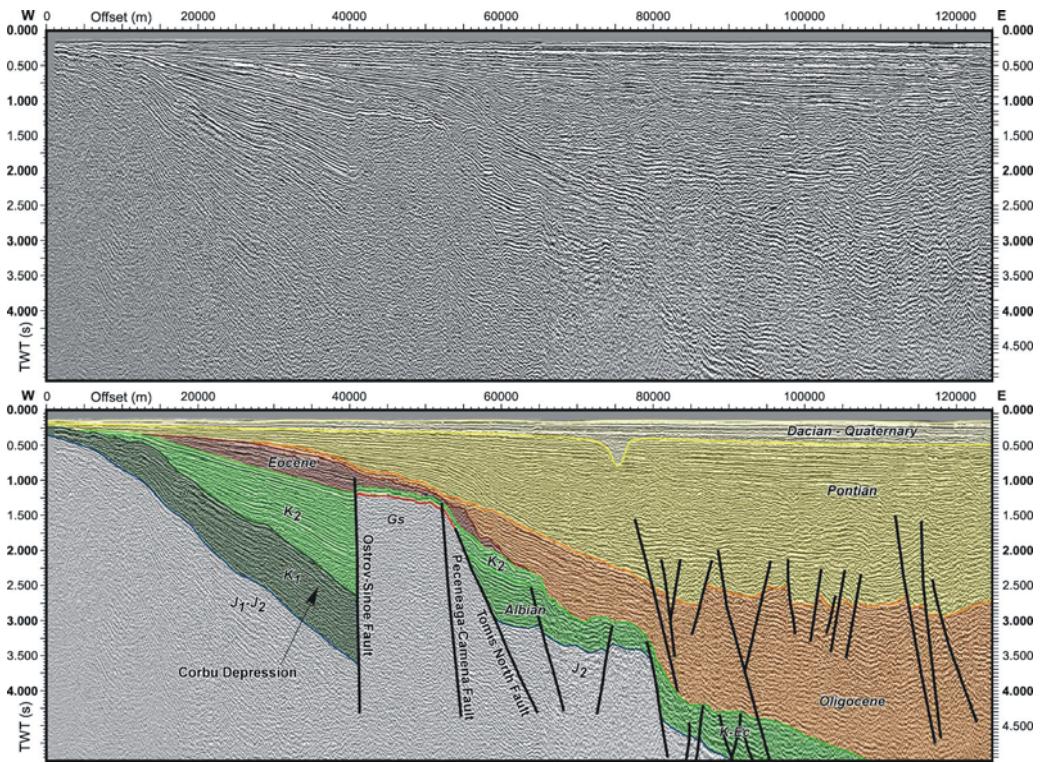

NE-SW seismic line 2 and interpretation. Note the high exaggeration of the vertical scale leading to an apparent subvertical position of faults in the profile. See Fig. 2 for profile location. Pz: Paleozoic, D: Devonian, O: Ordovician, S: Silurian, Ab: Albian, K-Eo: Cretaceous–Eocene, Eo1: Lower Eocene, Eo2: Upper Eocene.

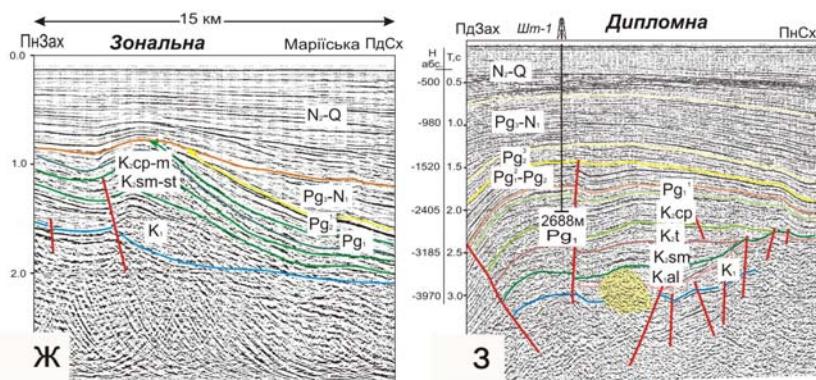

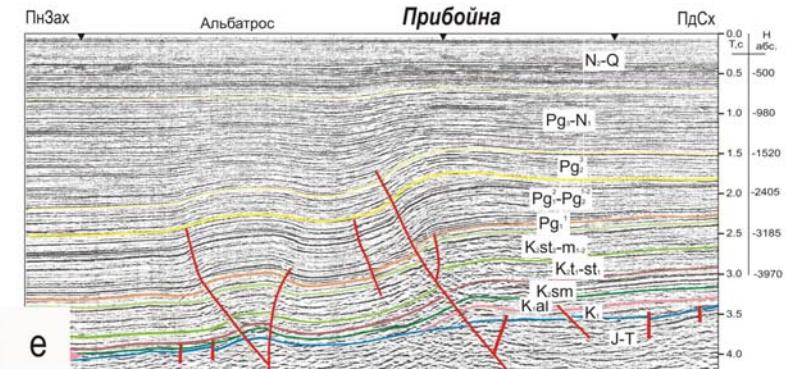

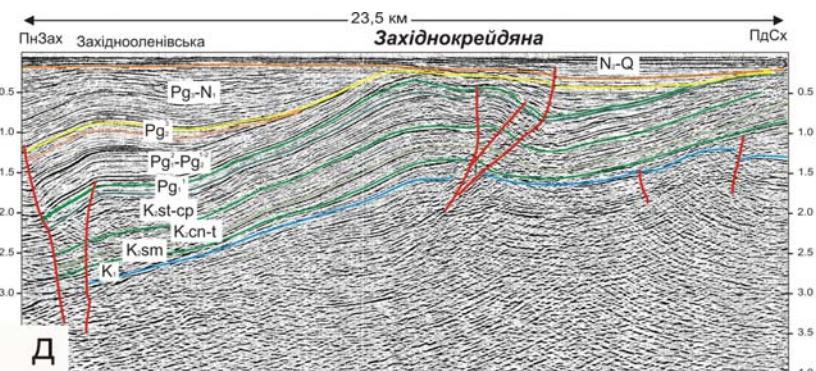

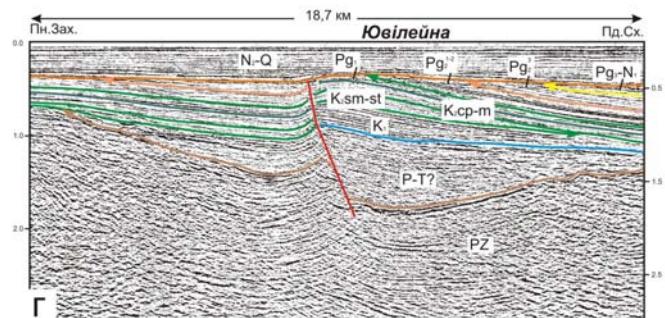

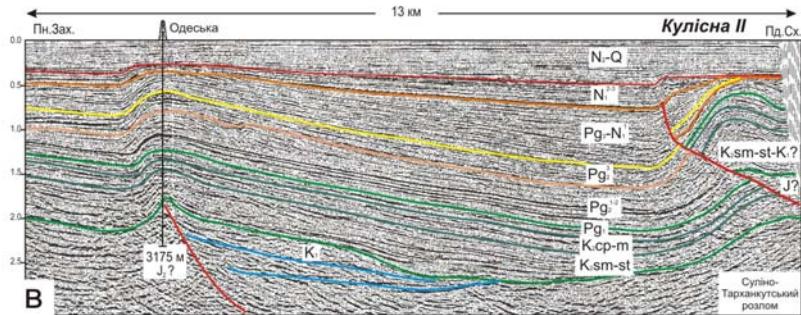

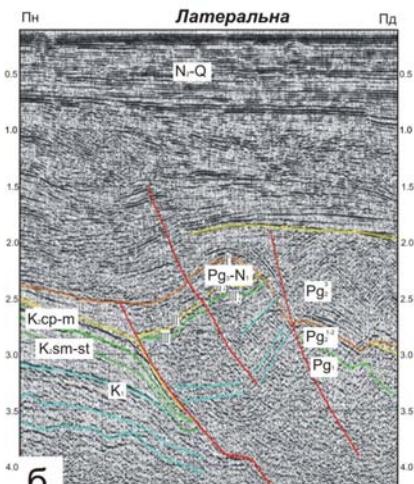

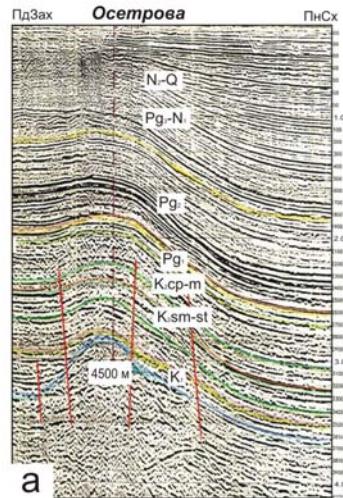

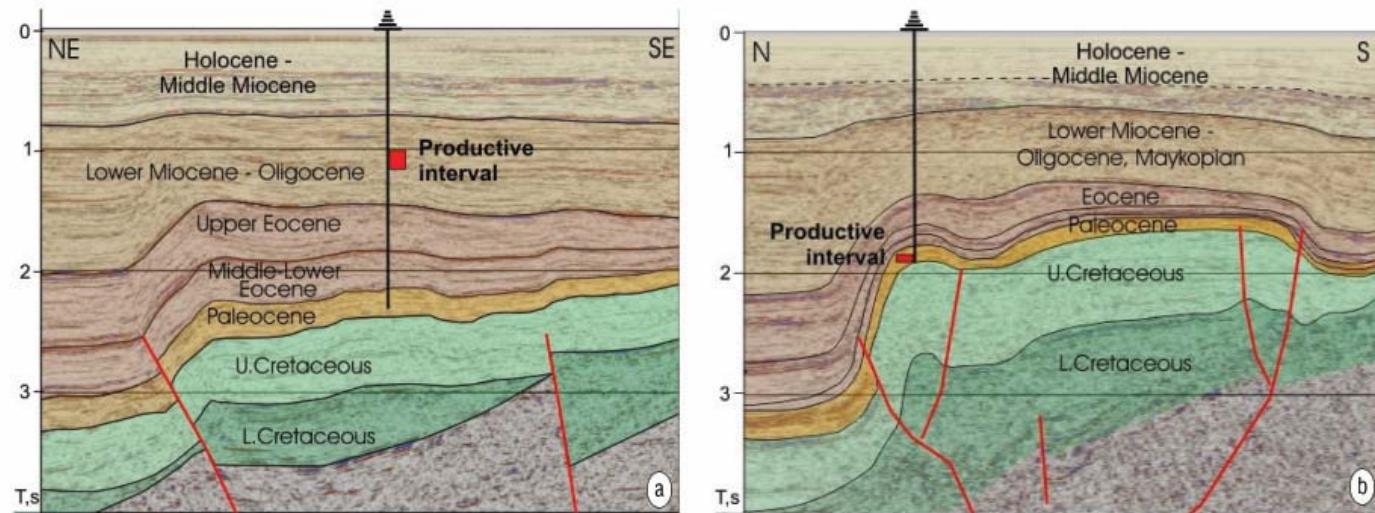

A. NW-SE seismic line 3 and interpretation. See Fig. 2 for profile location. Jr: Jurassic, Jr2-K1: Middle Jurassic-Lower Cretaceous, Ab: Albian, K2: Upper Cretaceous, Eo: Eocene; B. NW-SE seismic line 4 and interpretation. See Fig. 2 for profile location. Jr1: Lower Jurassic, Jr2: Middle Jurassic, Ab: Albian, K2: Upper Cretaceous.
C

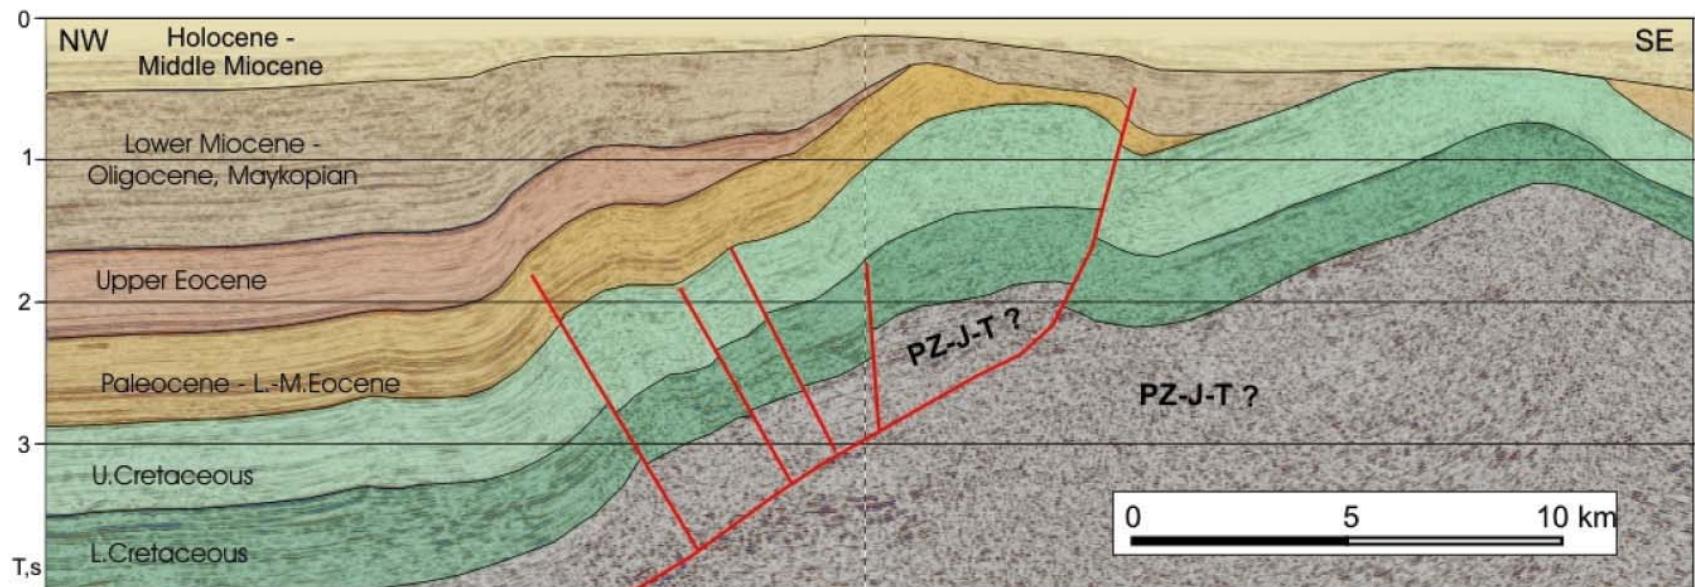

W-E seismic line 6 and interpretation. Note the high exaggeration of the vertical scale leading to an apparent subvertical position of faults in the profile. See Fig. 2 for profile location. Jr: Jurassic, K: Cretaceous, Eo: Eocene.

Одесский шельф (Стовба, Хрящевская и др.)

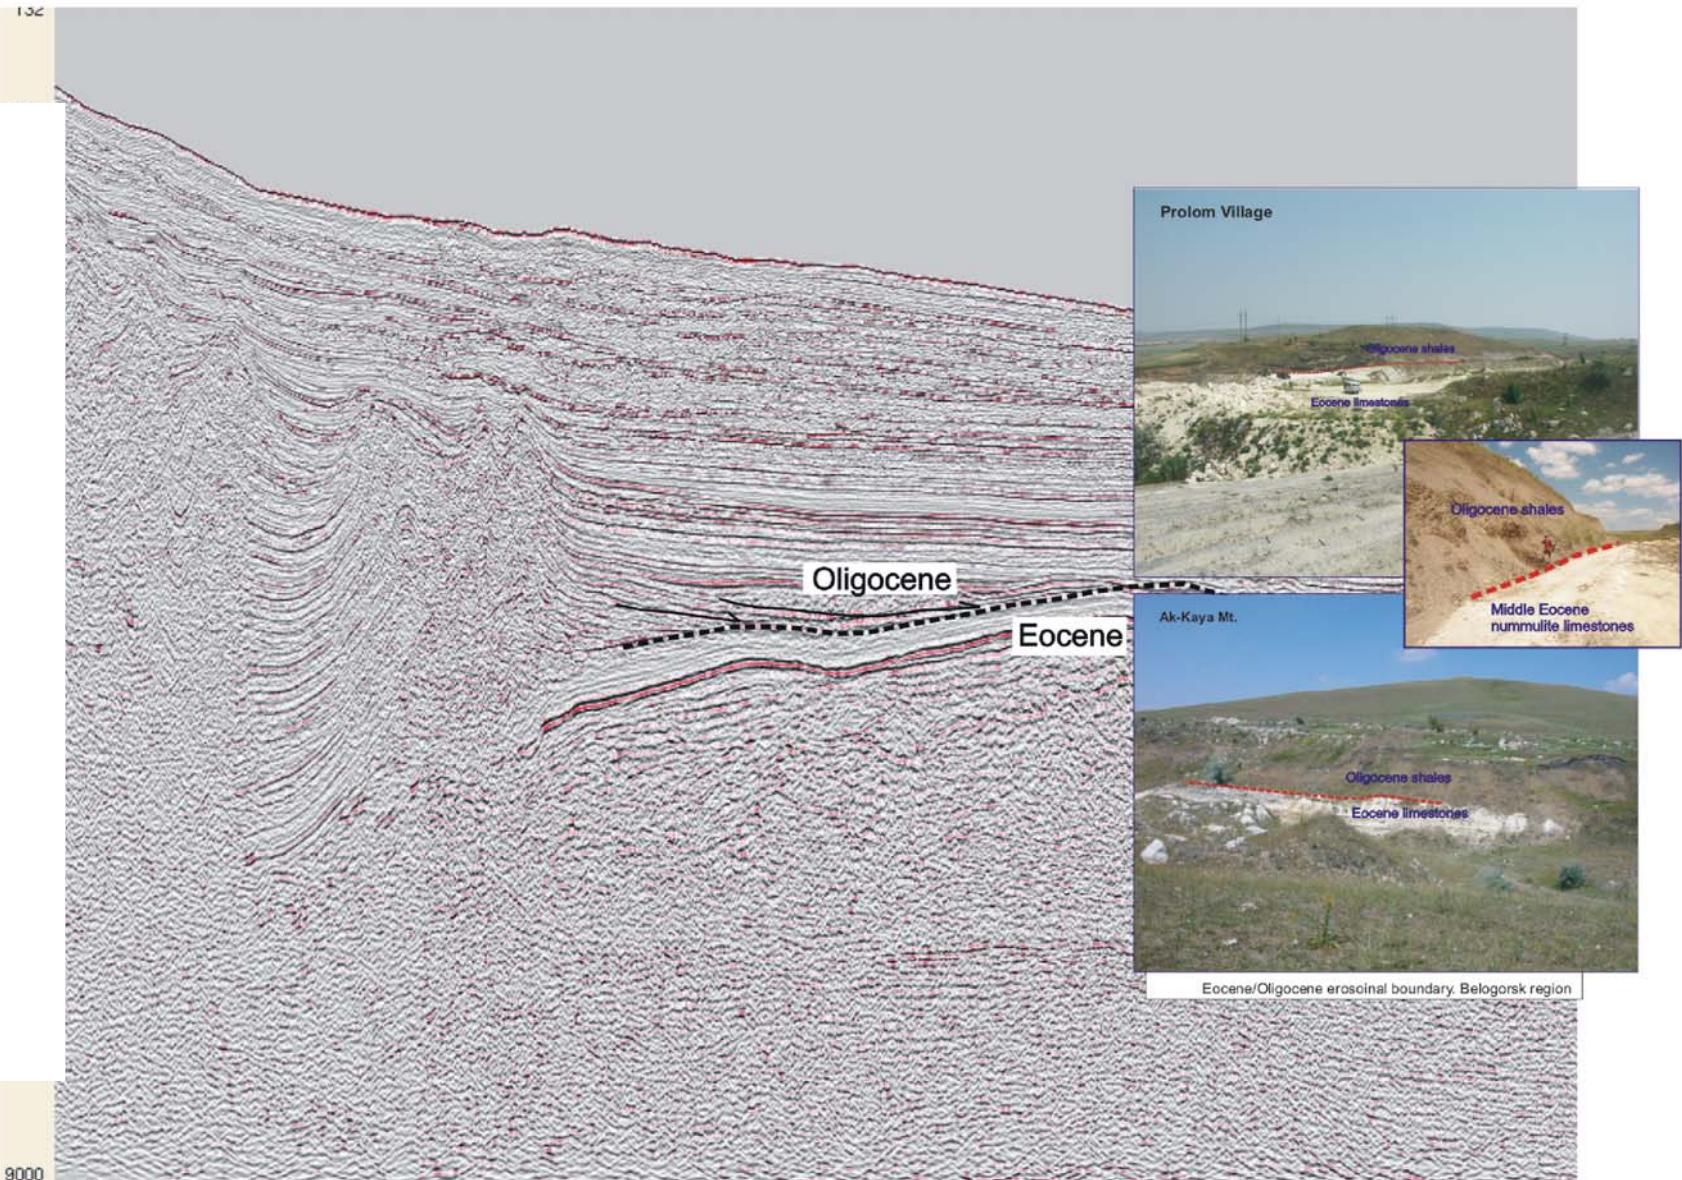

Typical inverted structures of the Odessa Shelf: (a) Krymskaya; (b) Shtormovaya.

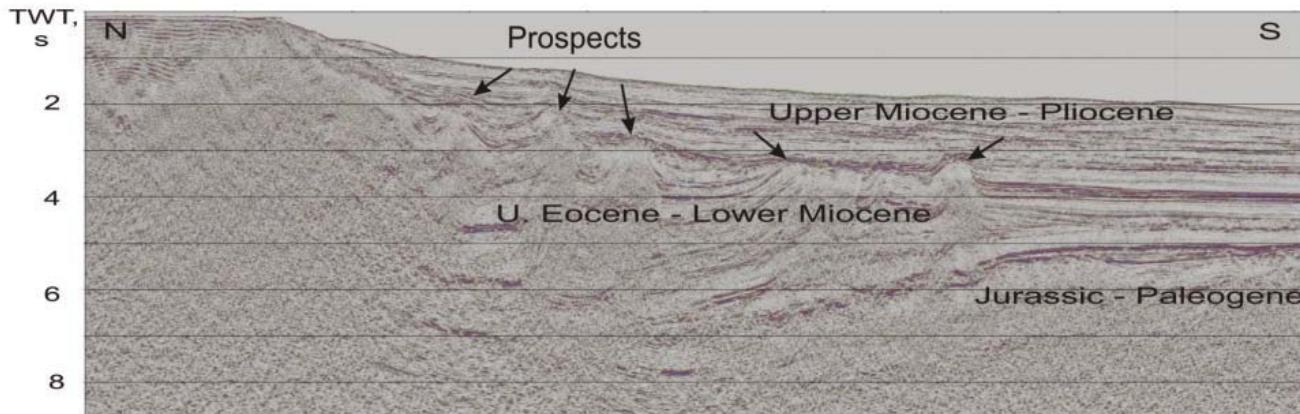

Structure of Zahidno-Kreydyana prospect (location on Figure 1).

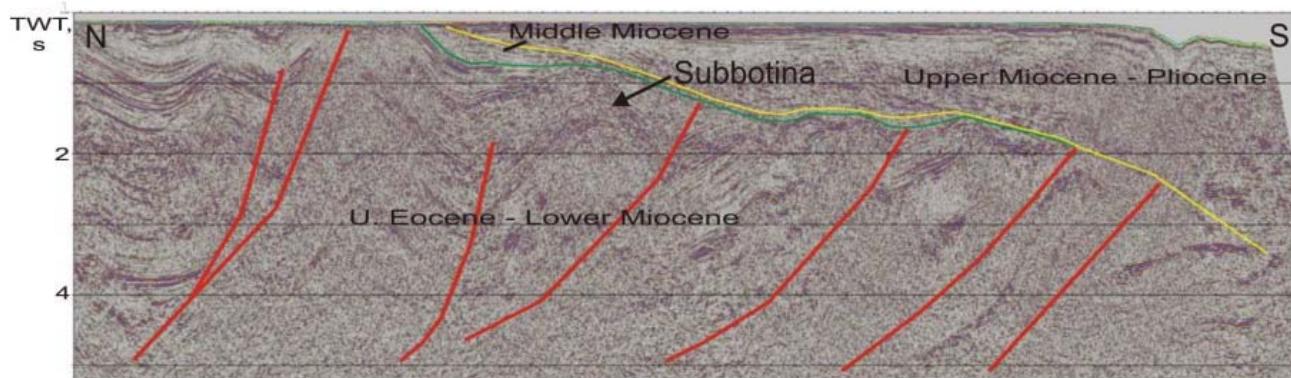

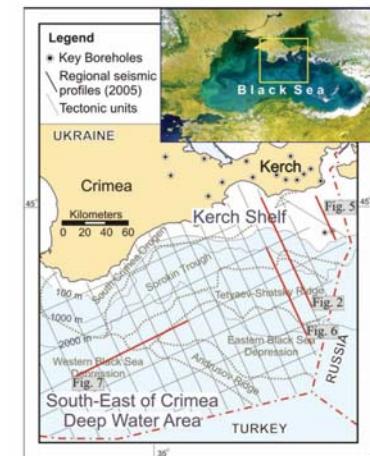

Прогиб Сорокина, майкоп образует краевой прогиб

Seismic view of Eocene/Oligocene unconformity.

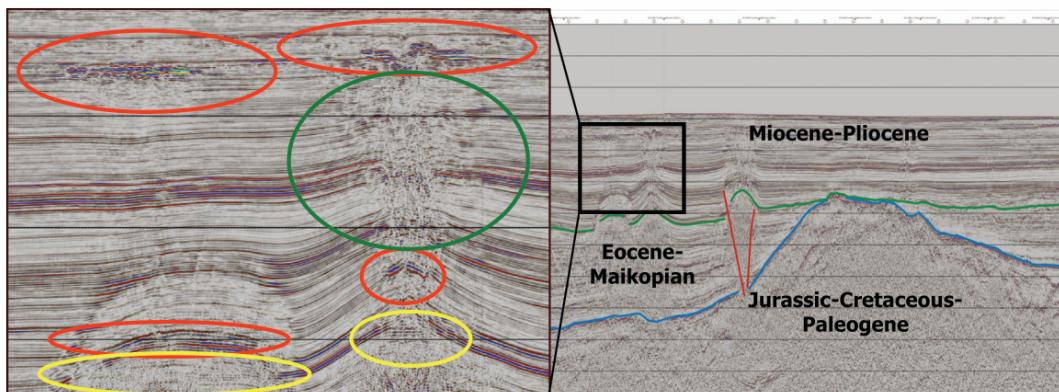

Regional seismic section. For location, see Figure 1.

Typical seismic expression of prospects and leads in the Kerch Shelf area. For location see Figure 1.

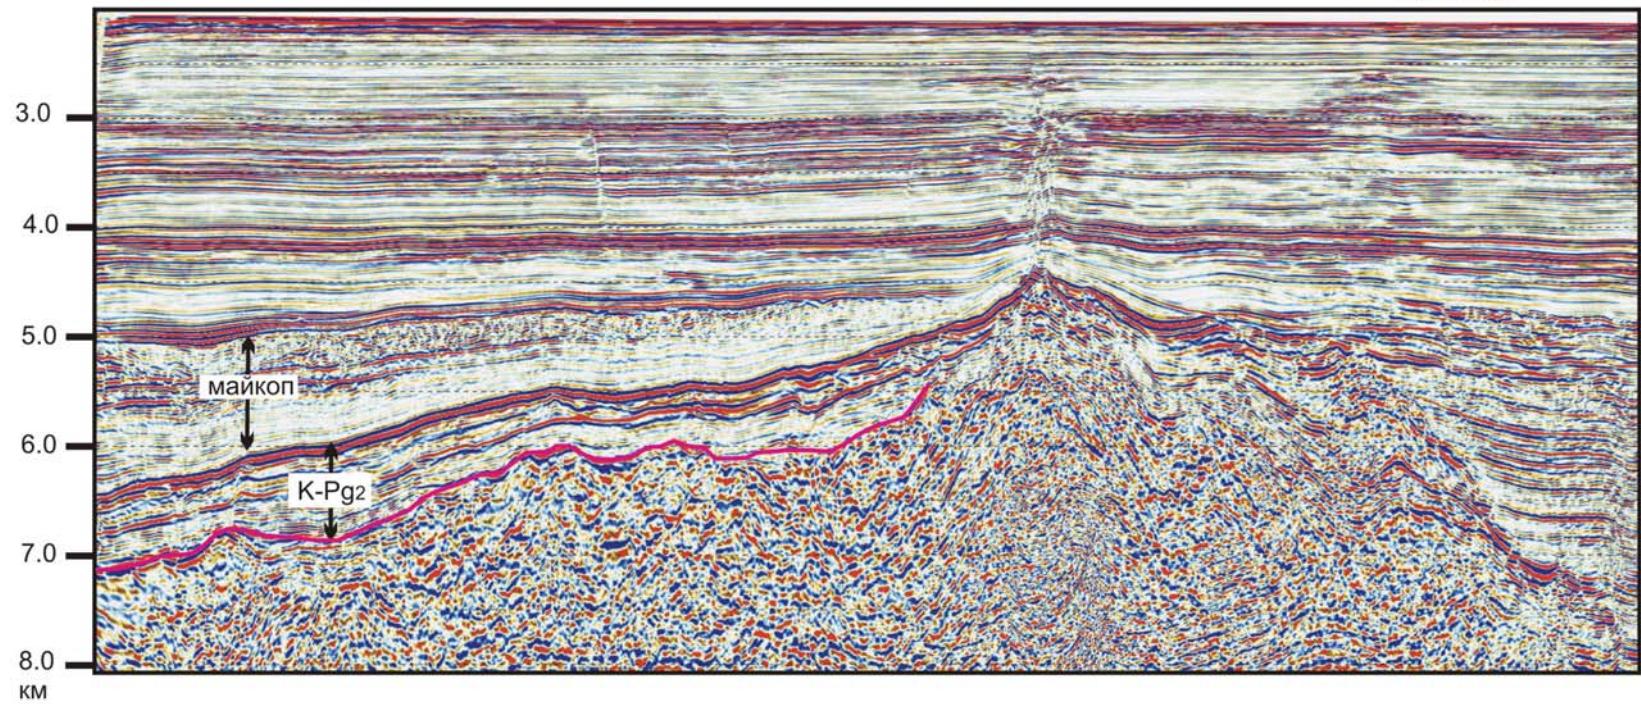

The Andrusov Ridge (right) and typical DHIs (direct hydrocarbon indicators), such as gas chimneys, shallow-gas accumulations, and flat spots, seen on the 2005 seismic reflection data (left). For location see Figure 1.

Продолжение дельты Днепра

L. Naudts et al. / Marine Geology 227 (2006) 177–199

Map of the study area with indication of the major geomorphological regions and canyons. Seep locations are plotted as black dots. The scars of the submarine landslides are emphasized by dashed lines and the position of two chimney fields is indicated by 2 horizontal arrows (1: Michaelis et al., 2002; 2: CRIMEA cruise 2004).

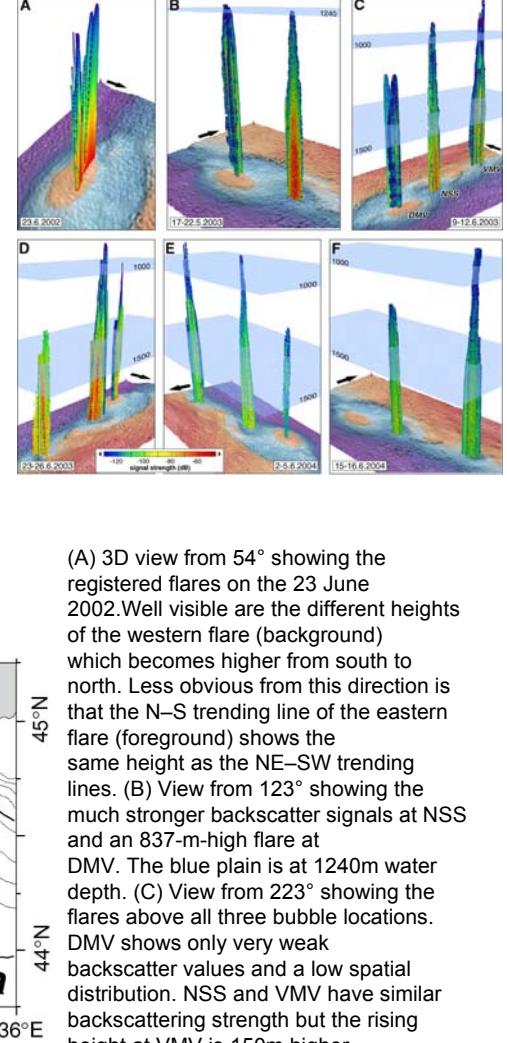

Bathymetric 3D map of the Danube Canyon, obtained from EM1000 data. The inset box shows a schematic representation of the canyon morphology, and the segments A to E separated along the canyon. Distinct paths of the thalweg in segment B are numbered 1 to 4. Shaded areas mark the steep canyon flanks.

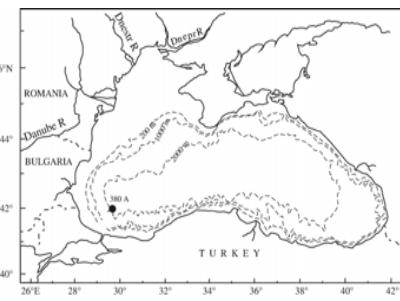

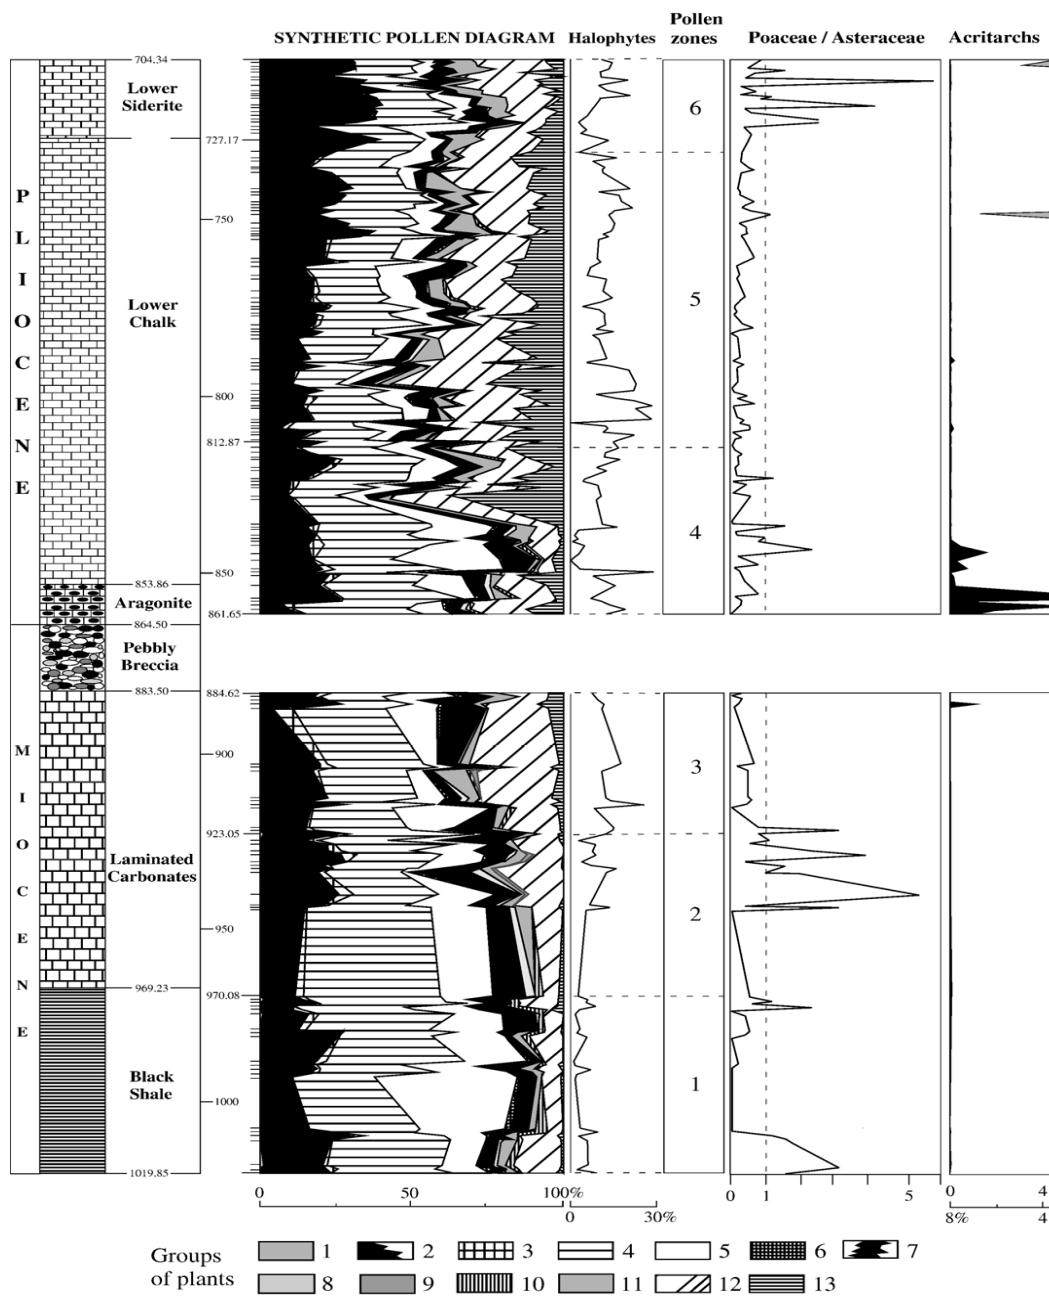

Paleogeographic map of the north-western Black Sea margin. Individual incised paleo channels identified on shallow seismic profiles were shot by the GeoEcoMar Institute and interpreted by Popescu et al. (2004). Areas characterised by dense occurrence of buried channels cluster in two main paleo-drainage systems.

(A) Position of the study area in the Black Sea, SE of the Crimea Peninsula (Ukraine). Little black dots indicate mud volcanoes, gray patches show the distribution of diapiric zones/faults (after Krastel et al. [34]). The sediments extruded from the mud volcanoes are clay-rich deposits from the Maikopian Formation that forms an Oligocene–Lower Miocene sequence of 4–5 km thickness [33]. (B) Bathymetric map of the study area with the locations of the investigated mud volcanoes Dvurechenskiy and Vodianitskiy (DMV, VMV) and the Nameless Seep Site (NSS). The overall depth range is from 2040 to 2140 m; the contour lines are in 2-m intervals with every 10-m annotated.

(A) 3D view from 54° showing registered flares on the 23 June 2002. Well visible are the different heights of the western flare (background) which becomes higher from south to north. Less obvious from this direction is that the N–S trending line of the eastern flare (foreground) shows the same height as the NE–SW trending lines. (B) View from 123° showing the much stronger backscatter signals at NSS and an 837-m-high flare at DMV. The blue plain is at 1240 m water depth. (C) View from 223° showing the flares above all three bubble locations. DMV shows only very weak backscatter values and a low spatial distribution. NSS and VMV have similar backscattering strength but the rising height at VMV is 150 m higher. Blue plains are in 1500 and 1000 m water depth. (D) View from 52° showing a strong but less high flare above VMV at the left and a very strong and high flare above NSS. The flare at DMV extends its height with respect to the previous observations, but becomes very thin above 1410 m water depth. (E) View from 329° showing the very high flare above NSS and VMV as well as the almost vanished flare above DMV with a rather th

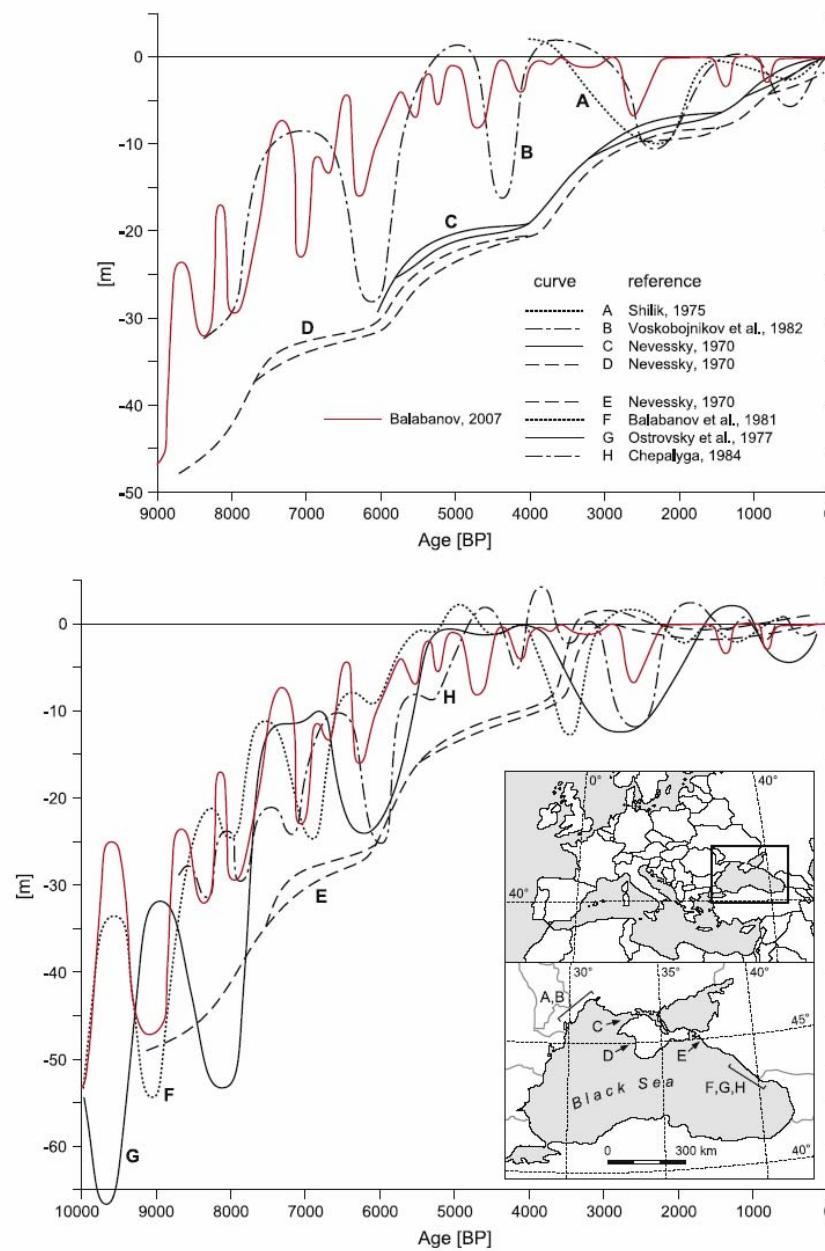

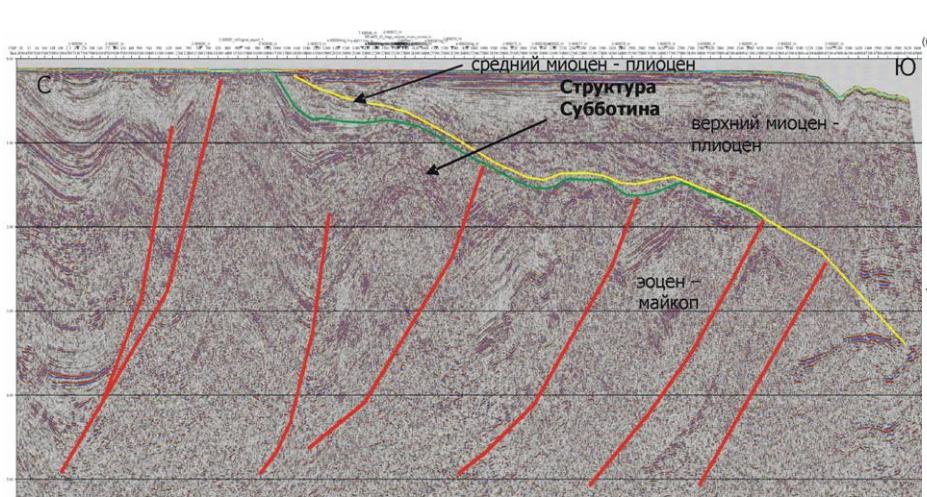

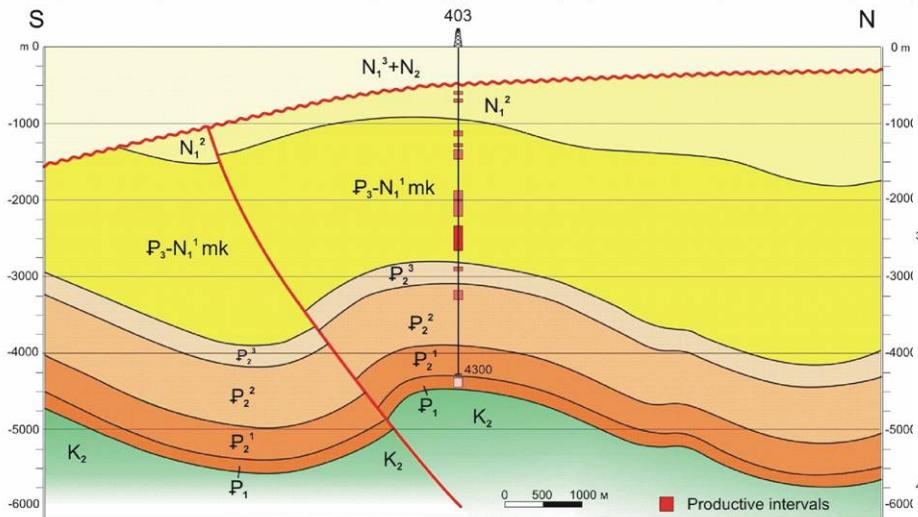

Fig. 6. Sea level curves for the Black Sea. Source: Pirazzoli (1991), Fig. 27, slightly modified.
